# Trichothecene mycotoxins inhibit mitochondrial translation – Implications for the mechanism of toxicity

**Anwar Bin-Umer**

Tumer Laboratory

SCAB USA 2011 Meeting

December 5<sup>th</sup>, 2011

# Rationale

- Trichothecenes contribute to the virulence of the pathogen.
- Toxicity is not simply due to cytosolic translation inhibition.
  - Mechanism of action is not yet fully understood.
- Identify molecular mechanisms underlying trichothecene toxicity → Identify genes conferring resistance to *Fusarium*-related diseases.
- “Model” the mechanism of toxicity and identify key players in it using a genome wide approach in yeast.
- Identify targets in *Arabidopsis thaliana* and then in wheat & barley.

## Gene deletions affecting mitochondrial function is the largest group resistant to Tcin

Yeast non-essential  
Gene deletion library  
(~5000 mutants)

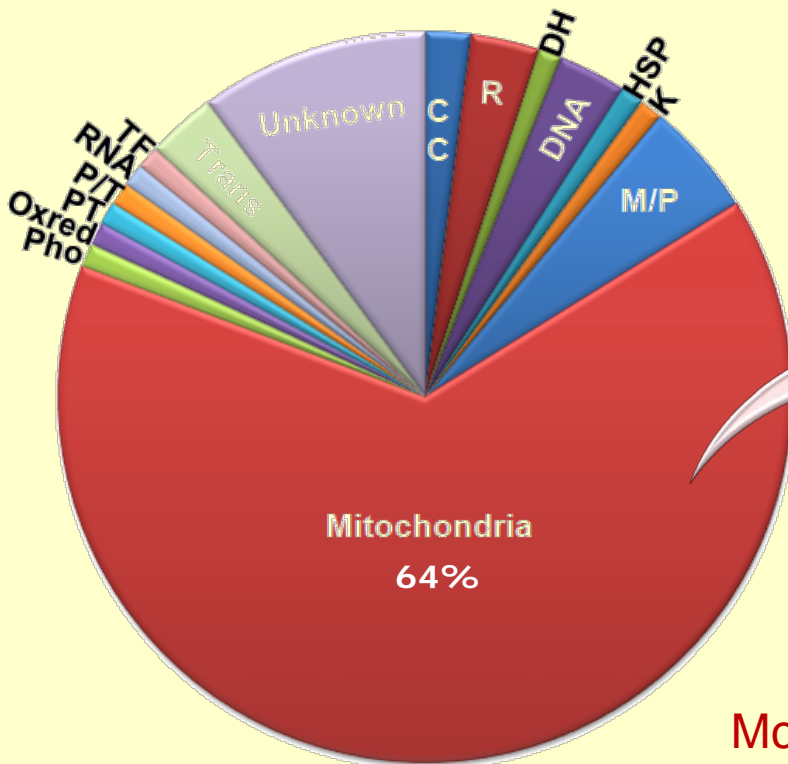

Mutants  
resistant to Tcin  
(138)

Deletions affecting  
mitochondrial  
functions (88)

- 43% associated with **mitochondrial translation.**
- Mitochondrial morphology related mutants were all defective in **membrane fusion.**

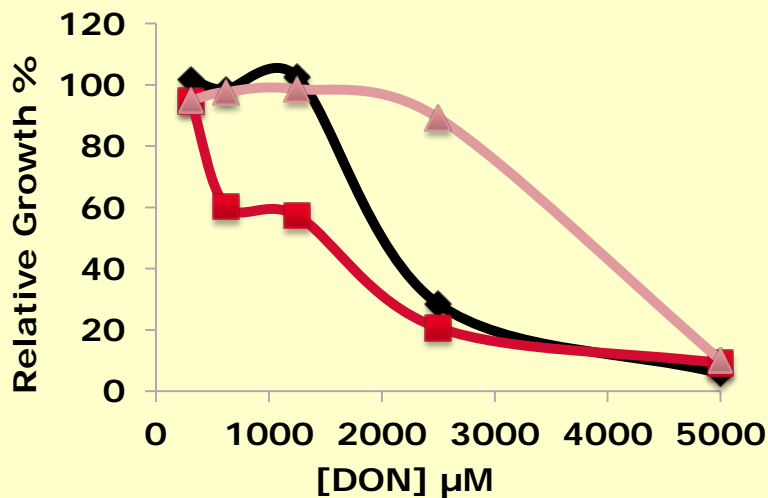

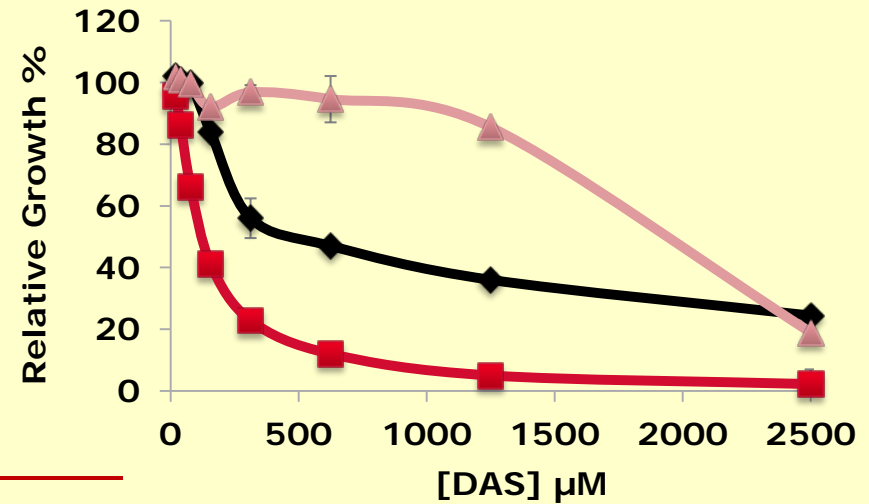

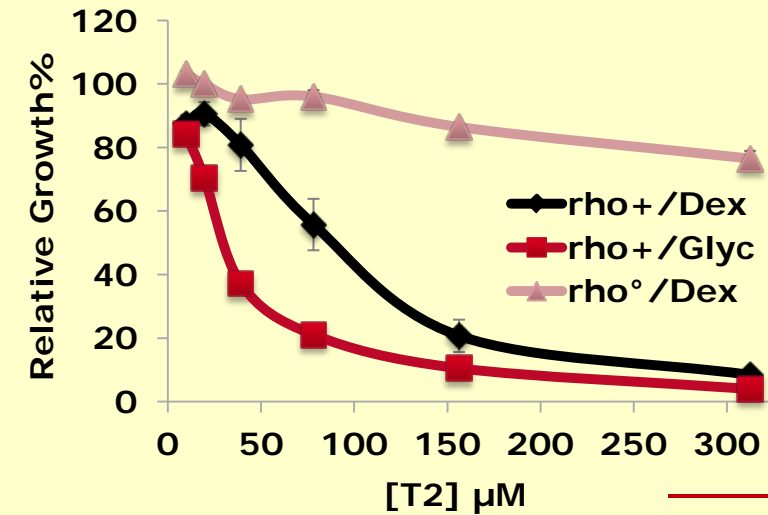

## How critical is mitochondria in trichothecene toxicity?

- 64% of the gene deletions conferring resistance to Tcin were associated with mitochondria.

**Functional mitochondria are necessary for survival when energy source is *non fermentable* glycerol (Glyc)**

## Mitochondria are critical for trichothecene toxicity

- Yeast cells are more sensitive to trichothecenes when carbon source is glycerol.
- $\rho^\circ$  (i.e. no functional mitochondria) cells are resistant to trichothecenes.

## Is mitochondrial translation targeted by trichothecenes?

- 43% of the gene deletions associated with mitochondria were classified as translation-related.

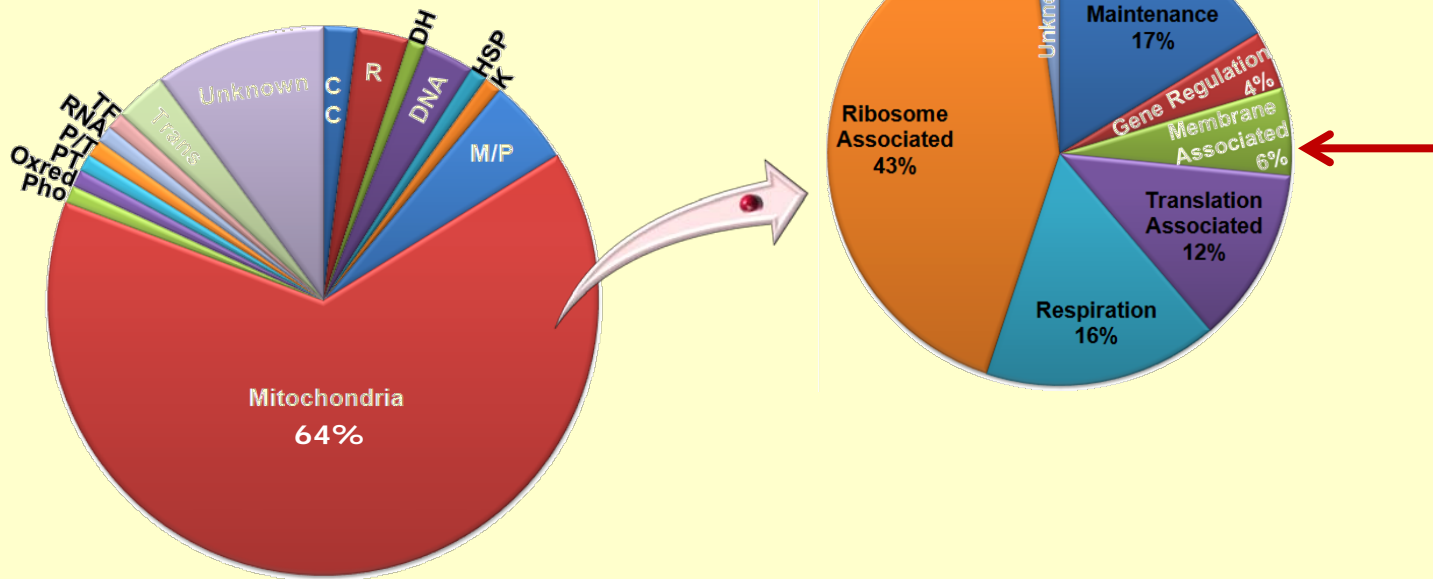

# Trichothecenes directly inhibit mitochondrial translation

- Mitochondria isolated from yeast cells were treated with trichothecenes for 10 minutes.

## Is mitochondrial membrane integrity damaged by trichothecenes?

- All mitochondrial morphology related mutants resistant to Tcin were defective in membrane fusion.

## Trichothecenes alter mitochondrial morphology

- To visualize mitochondrial morphology → Yeast cells transformed with mtGFP
- Untreated → tubular network.
- 6 h post treatment → fragmented mitochondria.

A. Control

B. 4  $\mu\text{M}$  Tcin

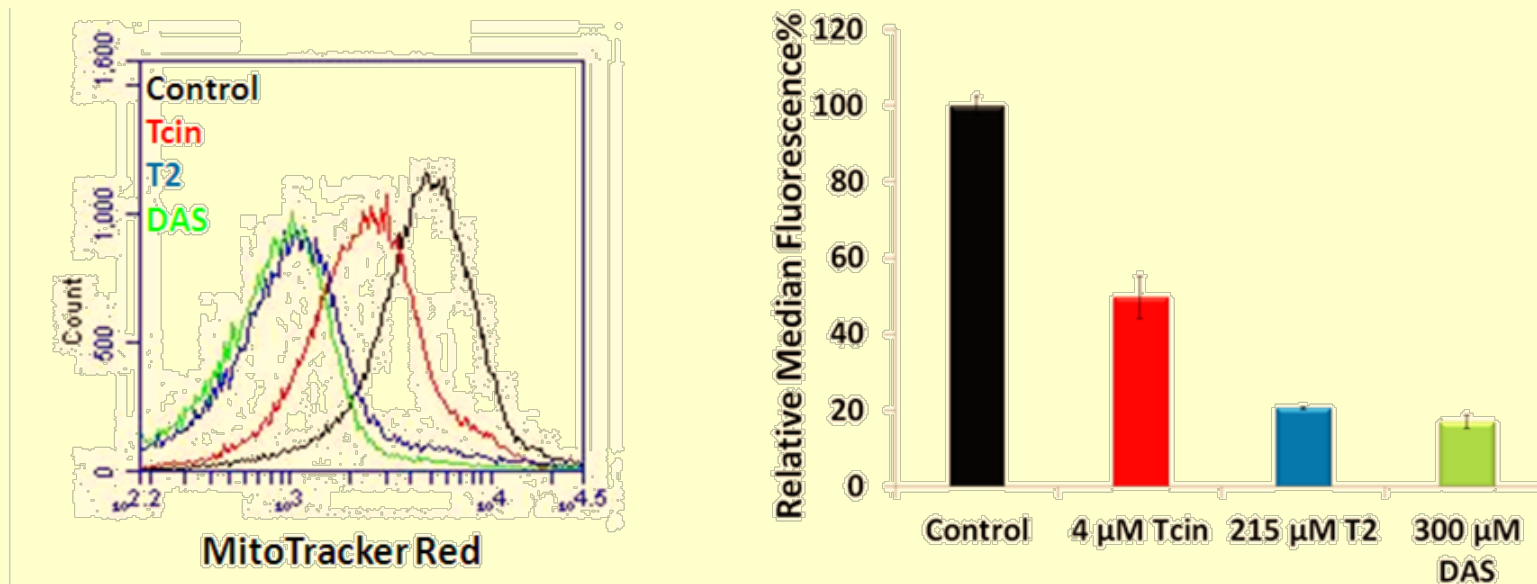

C. 215  $\mu\text{M}$  T2

D. 300  $\mu\text{M}$  DAS

## Trichothecenes cause mitochondrial membrane depolarization

- **Mitochondrial Membrane Potential** ( $\psi_{\text{mito}}$ ) : Biomarker for membrane integrity.
- **Membrane depolarization**  $\rightarrow$  fragmentation.
- **MitoTracker Red**: Only enters actively respiring mitochondria.
- Untreated  $\rightarrow$  High fluorescence  $\rightarrow \psi_{\text{mito}} \uparrow \rightarrow$  actively respiring mitochondria
- 6 h treatment  $\rightarrow$  Low fluorescence  $\rightarrow \psi_{\text{mito}} \downarrow \rightarrow$  dysfunctional mitochondria

## Is mitochondrial translation inhibition due to membrane damage?

- Trichothecenes inhibited translation in isolated mitochondria.
- Trichothecenes → membrane depolarization → fragmentation.

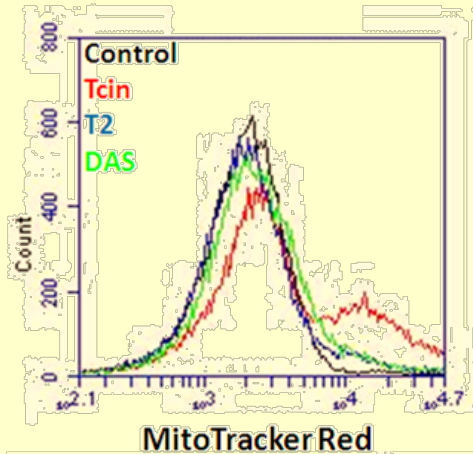

## Trichothecenes do *not* alter mitochondrial morphology at low doses.

- Identified low doses → no membrane damage.
- To visualize mitochondrial morphology → Yeast cells transformed with mtGFP.
- 6 h post treatment → no severe fragmentation.

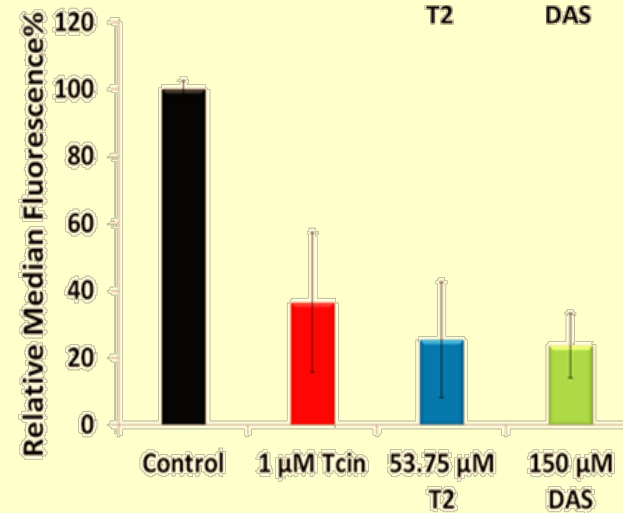

## Mitochondrial membrane damage occurs late during trichothecene toxicity

6h

18h

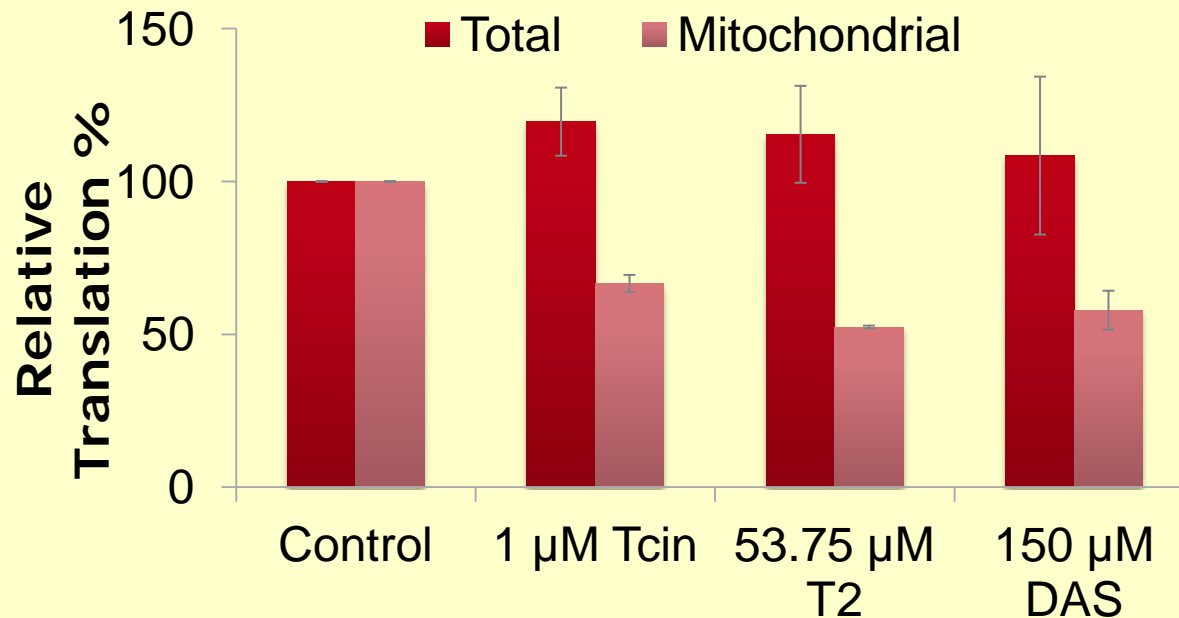

- 6 h treatment with low doses → no significant changes to  $\psi_{\text{mito}}$
- 18 h treatment with low doses → drop in  $\psi_{\text{mito}}$  (membrane depolarization)

**Is mitochondrial translation inhibited at these low doses?**

- Trichothecenes, at low doses, damage mitochondrial membrane integrity in a time dependent manner.

## Mitochondrial translation inhibition is not a secondary effect

- **6 h** post treatment with low doses:
  - Cytosolic translation is *not* inhibited
  - Mitochondrial membrane integrity is *not* damaged.
  - **Mitochondrial translation *is* inhibited.**
- Mitochondrial translation can be separated from cytosolic translation.

# Conclusion

Effect of trichothecenes:

Low doses

High doses

Early  
Time Point

**Mitochondrial  
Translation**

Late  
Time Point

**Membrane  
Damage**

**Cytosolic  
Translation**

- Mitochondrial translation is more sensitive to trichothecenes than cytosolic translation.
- During trichothecene toxicity mitochondrial translation is targeted before mitochondrial membranes and cytosolic translation.

# Implications

- Is mitochondrial translation inhibited in plant cells?
- Will protection against mitochondrial translation inhibition and membrane damage confer resistance?
- What is the role of chloroplast in trichothecene toxicity?
- How does the pathogen protect its own mitochondria?
- Mitochondria as potential target for engineering resistance against diseases like FHB.
