FHB Screening

- ◆ From >30,000 *Hordeum* accessions evaluated, <1% had resistance comparable to the 6- and 2-rowed controls

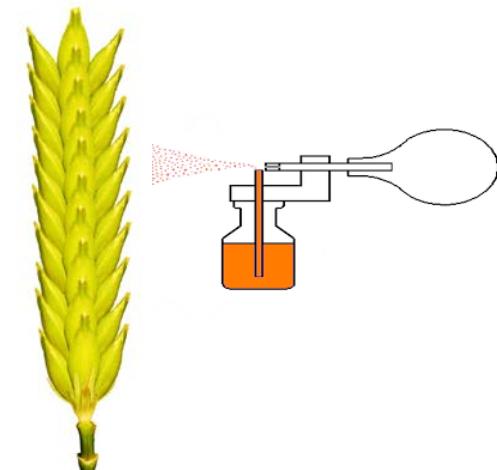

Variation for FHB reaction in China

Type I and Type II Resistance

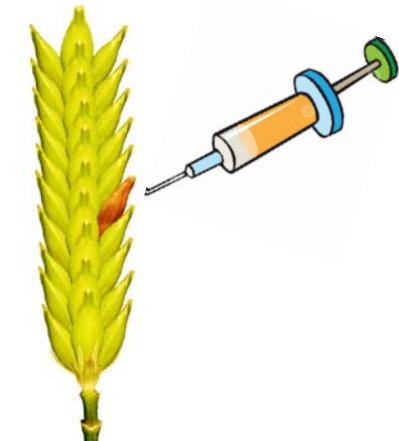

- ◆ Type I: resistance to initial infection

- Assayed by spray inoculation of spikes

- ◆ Type II: resistance to spread after initial infection

- Assayed by single floret inoculation of spikes

Infection Patterns

In the Field

Infection Patterns

- ◆ Barley often shows horizontal spread across a triplet and sometimes vertical

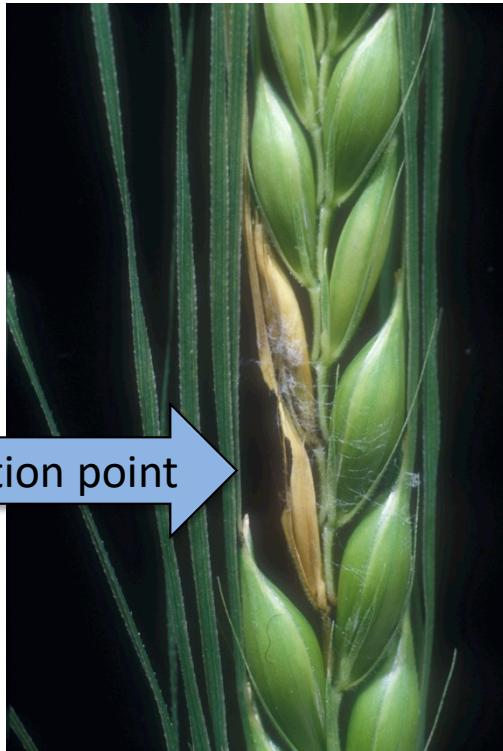

Infection Patterns

- ◆ Barley often shows horizontal spread across a triplet and sometimes vertical

Infection Patterns

- ◆ But this may be due to external mycelial spread or “nesting” and not spread through the rachis

- ◆ Harbin RILs: Sato et al., 2008

Meta-analyses of FHB Resistance Loci

- ◆ It is difficult to effectively utilize the many data collected from FHB resistance mapping populations without integration
- ◆ Meta-analysis: integration of previously identified QTLs from multiple linkage maps
- ◆ Integration of multiple QTLs on the same *consensus* map provides a comprehensive picture about the genetic control of FHB resistance and DON accumulation

Objectives

- ◆ Construct a consensus map based on previous mapping studies for FHB resistance
- ◆ Conduct a meta-analysis of QTL for FHB resistance and DON accumulation along with important agro-morphological traits
- ◆ Provide recommendations for the way forward in breeding for FHB resistance

Consensus Map Construction

Difficulties

- ◆ In some previous mapping populations:
 - Different markers used (i.e. SSR), limited allelic diversity, poor marker coverage, and small population sizes
- ◆ Need to integrate all markers types into one consensus map

Creating Consensus Maps

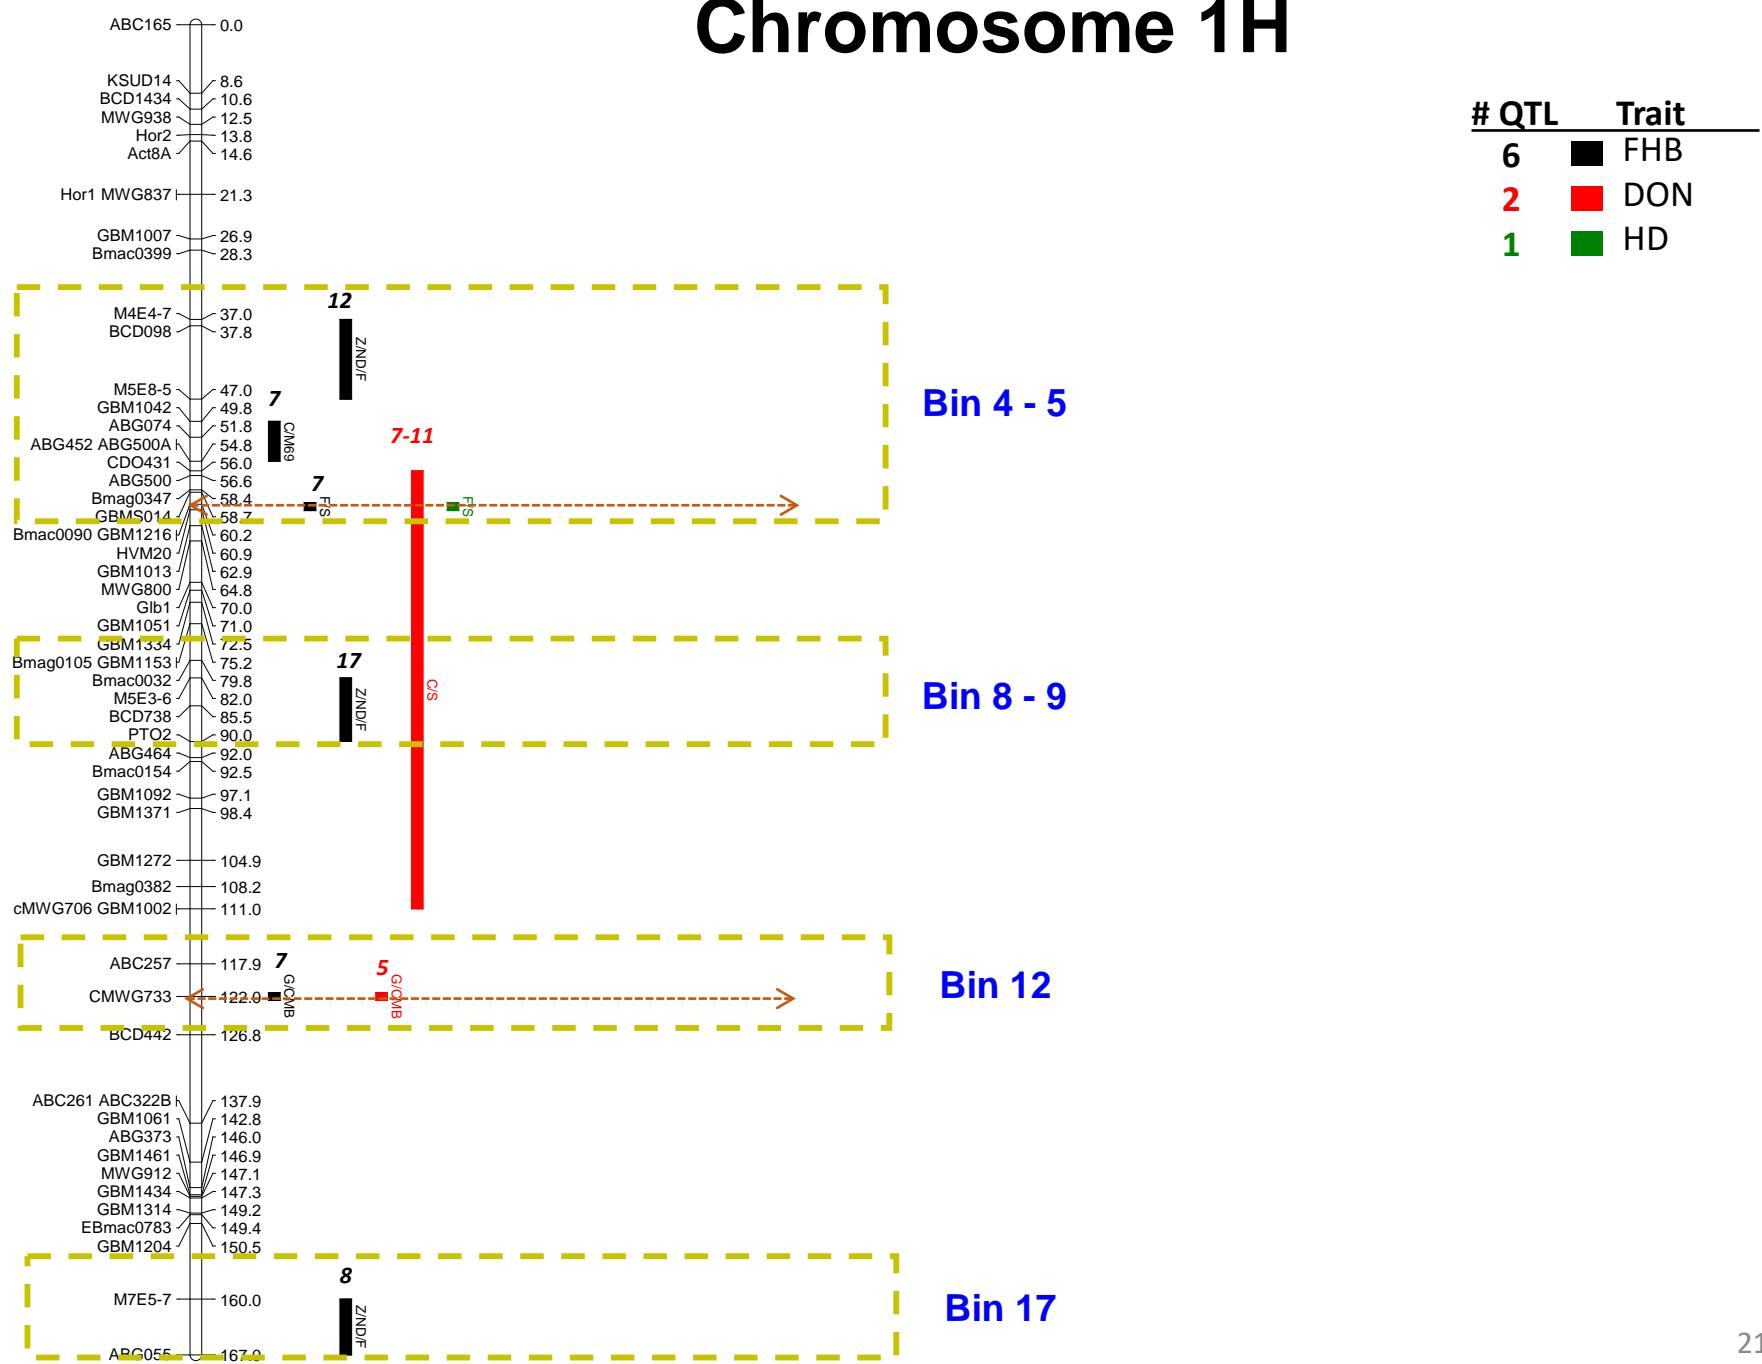

LPMerge Method

- ◆ Constructed using linear programming implemented in LPMerge package in R (Endelman and Plomion, 2014)
- ◆ Reduces mean error between linkage maps and the consensus map to ensure that marker order is preserved
- ◆ Advantages: removes marker constraints to resolve any conflicts in marker order
- ◆ Produces a graphical representation of marker order
- ◆ Eight maps were used to generate the consensus map

Summary Statistics for Consensus Map

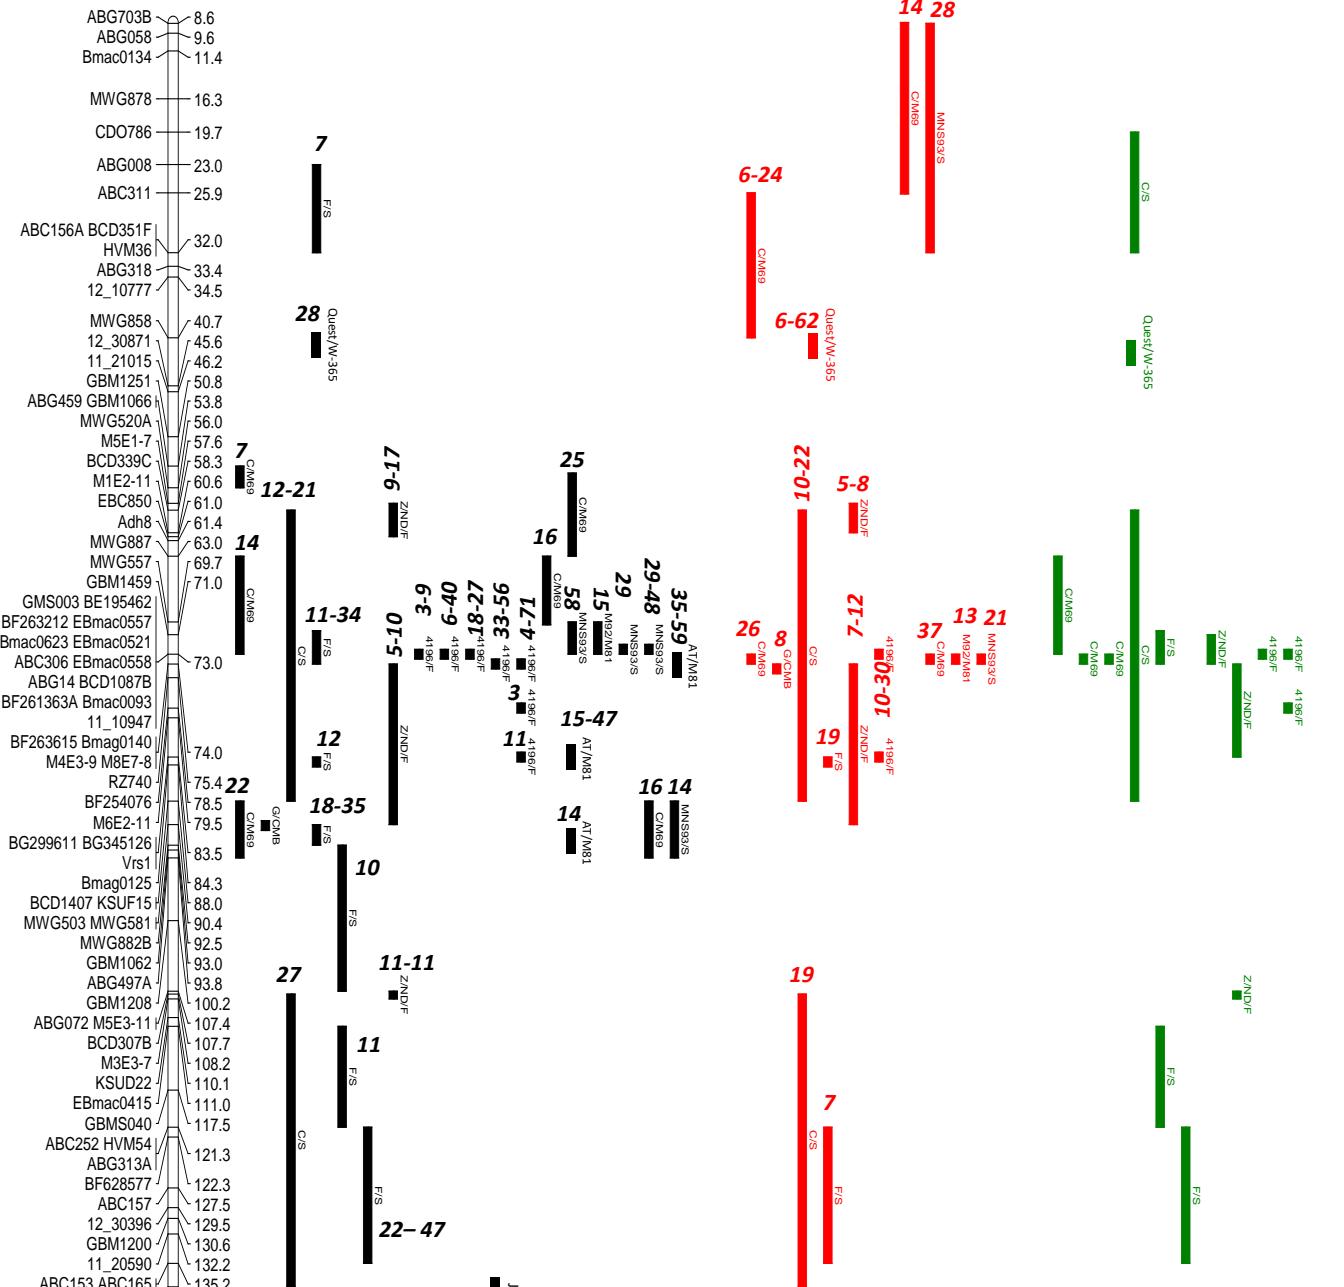

Population	Chromosome							Total
	1H	2H	3H	4H	5H	6H	7H	
Muñoz et al. consensus map	141.9	171.3	178.5	145.2	188.2	188.2	160.9

DON2H.11_1094 7	2H	73.0	8	

QTL Mapping

- ◆ Genetics of FHB severity and DON accumulation is complex: many QTL of small effect across genome
- ◆ Many QTL are not robust: detected in one environment only
- ◆ Number of agro-morphological traits co-localizing with QTL for FHB severity & DON accumulation strongly suggests pleiotropy
- ◆ Still, resistance QTL from various sources have been integrated into the breeding programs with some success

Breeding Lines with Reduced DON

Minnesota			North Dakota		
Variety / Line	Yield Bu/A	DON ppm	Variety / Line	Yield Bu/A	DON ppm

Genomic Selection

- ◆ Genomic selection aims to predict the genetic value of selection candidates based on the Genomic Estimated Breeding Value (GEBV)
- ◆ Predicted from high-density markers across the genome
- ◆ In contrast to MAS, GEBV is based on all markers across the genome, including those with minor effects as well as those major effects
- ◆ Thus, GEBV may capture more genetic variation for the target under selection

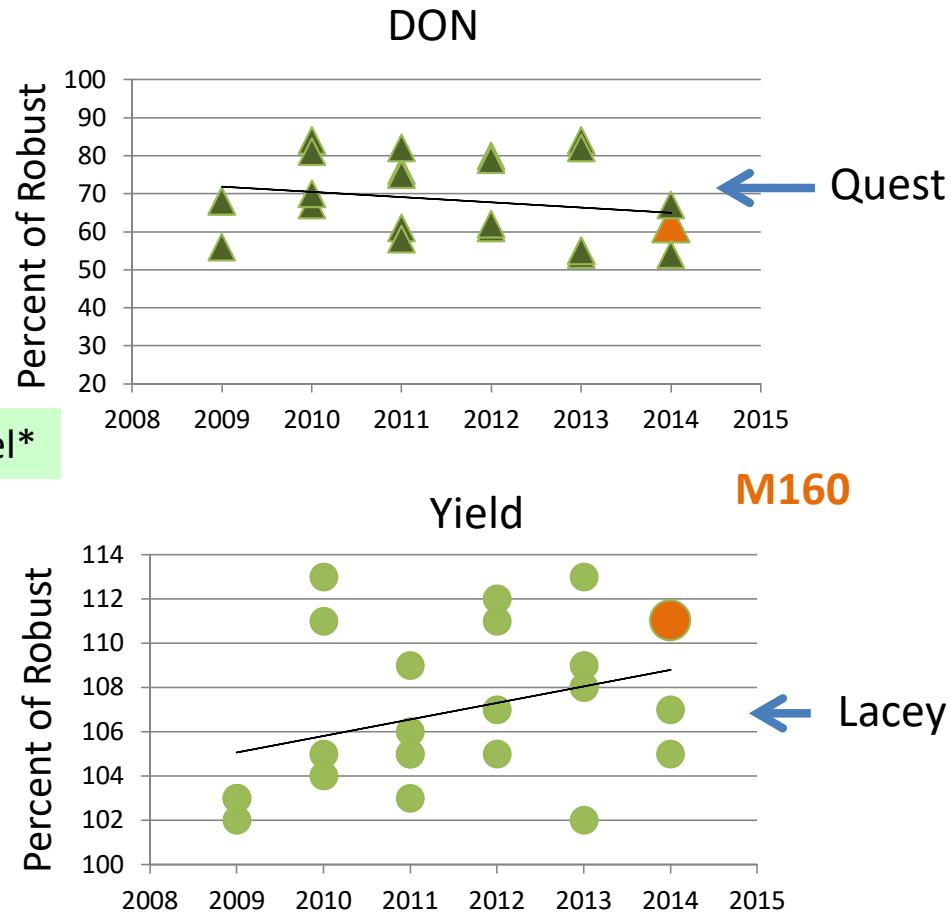

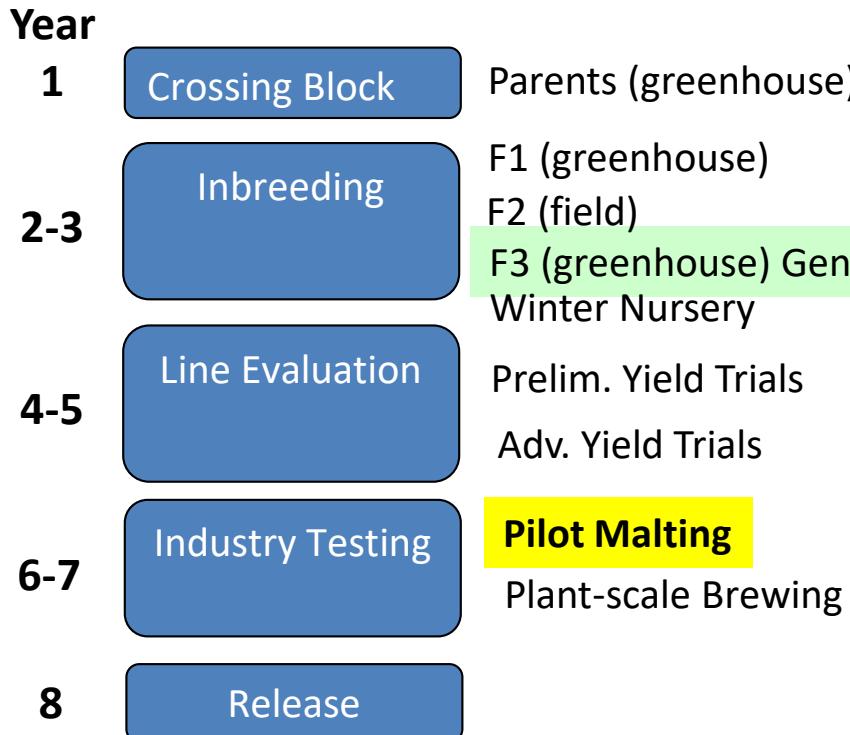

Genomic Selection for FHB Resistance

The Way Forward

- ◆ The greater uniformity of materials in breeding nurseries will parse out the contributions of agro-morphological traits on FHB and DON
- ◆ Evaluations done at multiple locations will provide greater confidence and validation of QTL effects
- ◆ Other traits important in breeding can be selected at the same time

Genomic Selection: DON & Yield

Spring Six-row Barley

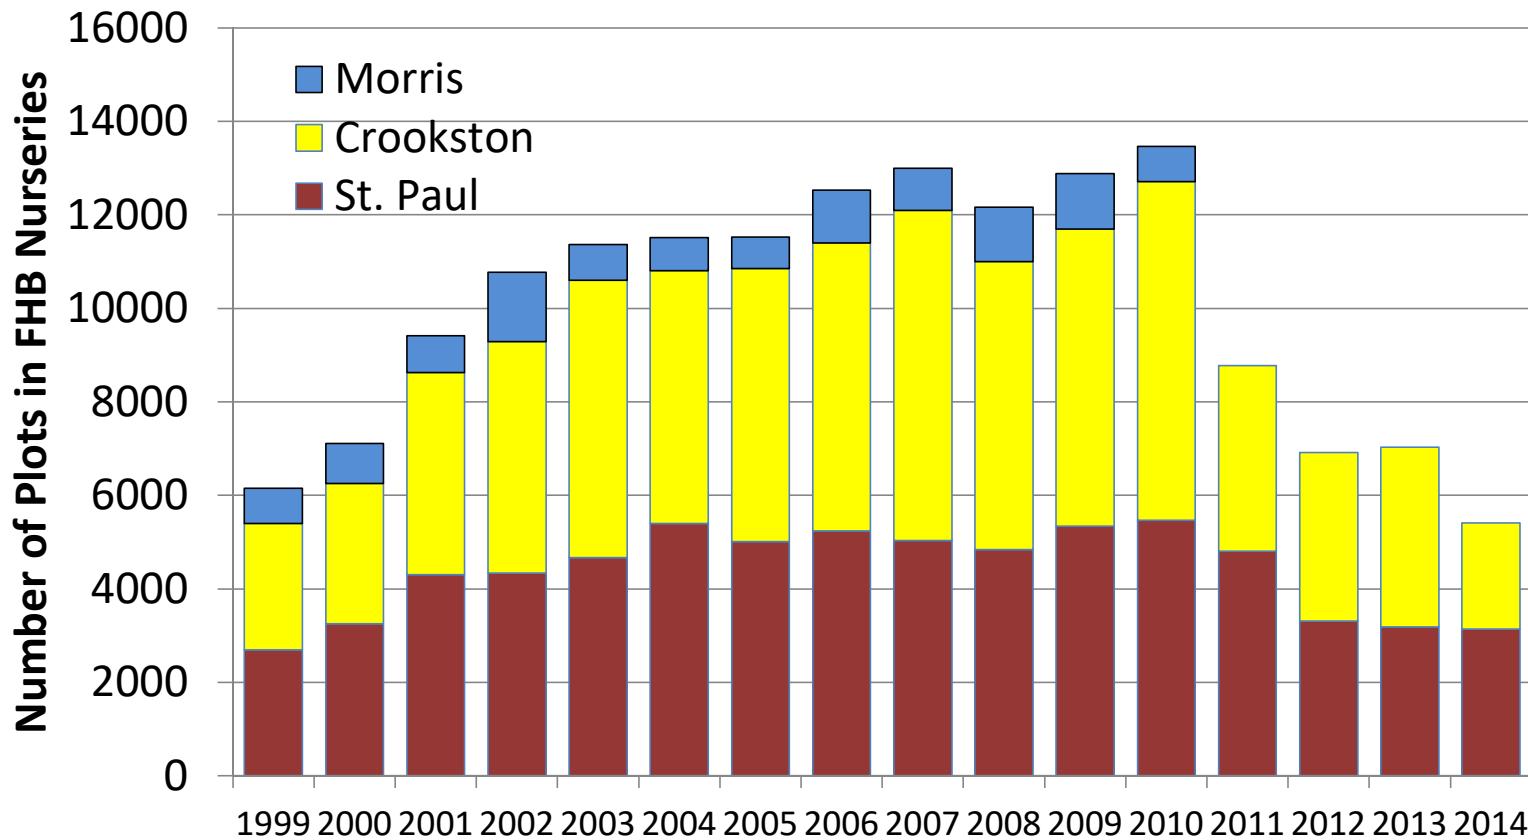

On Using Genomic Selection

- ◆ Genomic selection works--but not all the time
- ◆ Accuracy is greater when the training population is more closely related to the prediction population
- ◆ Technical/logistical issues are not trivial
- ◆ Greatest impacts:
 - Cost of genotyping < less than phenotyping
 - GS can shorten breeding cycle
 - Morale!

Genomic Selection has Reduced Field Resources for FHB Screening

Summary

- ◆ Biparental and association mapping revealed many QTL for low FHB severity and DON across the genome
- ◆ Although many QTL co-locate with agro-morphological traits, some have contributed to cultivars with low FHB and DON, e.g. Quest et al.
- ◆ Genomic selection is a promising method to increase the accuracy and shorten the breeding cycle for selection of FHB resistance, thereby hastening the release of new, improved varieties

Positive Changes on the Horizon?

- ◆ Two-rowed barley is now the preferred type for malting in the Upper Midwest
- ◆ Autumn-sown facultative barleys are now being bred for the Upper Midwest
- ◆ Two-rowed barleys generally suffer less FHB and DON than six-rowed types
- ◆ Autumn-sown barleys may often escape the most conducive conditions for FHB in the summer
